.IMMUNO BIOCHEMISTRY-1

Test Name With Methodology	Result	Unit	Biological Ref.Interval
Hepatitis A virus-IgM Antibodies			
Hepatitis A Antibody (Anti-HAV) IgM Serum ECLIA	10.90	COI	<1.0 Negative

Comments:

This test measures IgM antibodies against Hepatitis A Virus . The hepatitis A virus (HAV) is a small, 27 nm RNA virus. It is transmitted primarily by the fecal-oral route, and is found more commonly in situations where unsanitary conditions and/or close contact among individuals exist. Contaminated food and water are frequent means of transmission. Although ~70% of children aged < 6 years with HAV infection are asymptomatic, older children and adults usually have symptoms and 70% are jaundiced. The incubation period is short, averaging 25 days and ranging from 15-45 days. Serum IgM antibody to the hepatitis A virus (anti-HAV) appears at about four weeks after initial infection and usually persists for 2-6 months as the initial phase of the immune response. Subsequently, only IgG antibodies are detected. Serum IgG antibody to HAV generally persists for lifetime, conferring immunity to further type A infection. HAV is typically self-limited and does not lead to chronic liver disease or to a persistent carrier state.

Test Name With Methodology	Result	Unit	Biological Ref.Interval
IMMUNOASSAY			
Hepatitis E virus-IgM Antibodies (HEV IgM)			
HEV IgM Serum, ELISA	0.01	COV	<0.16 NEGATIVE >0.16 POSITIVE

Comments:

This test measures the IgM antibody against Hepatitis E Virus. Hepatitis E is also called Non A, non B ET Hepatitis. This virus can infect by digestive system. Anti-HEV IgM can occur in the blood, or plasma, or serum of acute hepatitis E patient. Hepatitis E virus (HEV) causes self-limiting acute viral hepatitis and is the major cause of enterically transmitted non-A, non-B hepatitis. Humans are the natural hosts of HEV, but animals such as pigs (and may be other species) are considered reservoirs. HEV infection is most often seen in young to middle-aged adults (15-40 years old). A significant proportion of pregnant women infected with HEV (up to 25%) developed fatal hepatitis. The virus is transmitted primarily by the fecal-oral route and fecally contaminated drinking water is the most commonly documented vehicle of transmission.

Anti-HEV IgM and IgG titres continue to increase in the asymptomatic phase. The anti-HEV IgM titre peaks during the symptomatic phase and declines thereafter to baseline values within 3-6 months of symptomatic disease. The anti-HEV IgG titre remains detectable for 2-13 years
