.IMMUNO BIOCHEMISTRY-1

Test Name With Methodology	Result	Unit	Biological Ref.Interval
Hepatitis A virus-IgM Antibodies			
Hepatitis A Antibody (Anti-HAV) IgM Serum: ECLIA	0.201	COI	<1.0 Negative

Comments:

This test measures IgM antibodies against Hepatitis A Virus . The hepatitis A virus (HAV) is a small, 27 nm RNA virus. It is transmitted primarily by the fecal-oral route, and is found more commonly in situations where unsanitary conditions and/or close contact among individuals exist. Contaminated food and water are frequent means of transmission. Although ~70% of children aged < 6 years with HAV infection are asymptomatic, older children and adults usually have symptoms and 70% are jaundiced. The incubation period is short, averaging 25 days and ranging from 15-45 days. Serum IgM antibody to the hepatitis A virus (anti-HAV) appears at about four weeks after initial infection and usually persists for 2-6 months as the initial phase of the immune response. Subsequently, only IgG antibodies are detected. Serum IgG antibody to HAV generally persists for lifetime, conferring immunity to further type A infection. HAV is typically self-limited and does not lead to chronic liver disease or to a persistent carrier state.

Hepatitis B surface antigen (HBsAg) ECLIA			
Hepatitis B Surface Antigen(HBS Ag) ECLIA	0.459	COV	< 0.90 Negative

Serum, Electro Chem Luminescent Immuno Assay

COMMENTS:

For diagnostic purposes, the results should always be assessed in conjunction with the patient's medical history, clinical examination and other findings. This immunoassay for the in vitro qualitative determination of hepatitis B surface antigen (HBsAg) in human serum and plasma.

Hepatitis B is a potentially life-threatening liver infection caused by the hepatitis B virus (HBV). It is transmitted through contact with the blood or other body fluids of an infected person. Hepatitis B surface antigen (HBsAg) is a polypeptide component of the external envelope of HBV, presenting various immunogenic determinants. After infection, HBsAg is the first immunologic marker detectable in serum and is usually present weeks before the onset of clinical symptoms and the appearance of other biochemical markers.

Test Name With Methodology	Result	Unit	Biological Ref.Interval
Hepatitis C virus-Total Antibodies (ECLIA)			
Hepatitis C Total Ab (Anti-HCV) ECLIA Serum, Electro Chemi Luminescent Immuno Assay	0.045	COI	<0.9 Non-Reactive 0.9 to < 1.0 Borderline 1.0 Reactive

Comments:

Hepatitis C (HCV) is an RNA virus of Flavivirus group transmitted via blood transfusions, transplantation, injection drug users, accidental needle punctures in healthcare workers, dialysis patients and rarely from mother to infant. 10% of new cases show sexual transmission. As compared to HAV & HBV, chronic infection with HCV occurs in 85% of infected individuals. In high risk populations, the predictive value of Anti HCV for HCV infection is > 99% whereas in low risk populations it is only 25%.

Note:

1. The Anti-HCV Antibody assay is an in vitro diagnostic test for the **qualitative** detection of antibodies to hepatitis C virus (HCV) in human serum and plasma.
2. False positive results are seen in Autoimmune diseases, Rheumatoid factor, Hypergammaglobulinemia, Paraproteinemia, passive antibody transfer, Anti- idotypes & Anti superoxide dismutase
3. False negative results are seen in early Acute infection, Immunosuppression & Immuno-incompetence.
4. HCV RNA PCR recommended in all Reactive results to differentiate between past and present infection.

Uses: Indicator of past or present infection, but does not differentiate between Acute / Chronic / Resolved infection ?
 Routine screening of low and high prevalence populations including blood donors.

IMMUNOASSAY			
Hepatitis E virus-IgM Antibodies (HEV IgM)			
HEV IgM Serum, ELISA	0.03	COV	<0.16 NEGATIVE >0.16 POSITIVE

Comments:

This test measures the IgM antibody against Hepatitis E Virus. Hepatitis E is also called Non A, non B ET Hepatitis. This virus can infect by digestive system. Anti-HEV IgM can occur in the blood, or plasma, or serum of acute hepatitis E patient. Hepatitis E virus (HEV) causes self-limiting acute viral hepatitis and is the major cause of enterically transmitted non-A, non-B hepatitis. Humans are the natural hosts of HEV, but animals such as pigs (and may be other species) are considered reservoirs. HEV infection is most often seen in young to middle-aged adults (15-40 years old). A significant proportion of pregnant women infected with HEV (up to 25%) developed fatal hepatitis. The virus is transmitted primarily by the fecal-oral route and fecally contaminated drinking water is the most commonly documented vehicle of transmission.

Anti-HEV IgM and IgG titres continue to increase in the asymptomatic phase. The anti-HEV IgM titre peaks during the symptomatic phase and declines thereafter to baseline values within 3-6 months of symptomatic disease. The anti-HEV IgG titre remains detectable for 2-13 years
