Estradiol (E2) is the most important form of estrogen found in the body. Most of it is made in and secreted from the ovaries, adrenal cortex, and placenta. Estradiol is responsible for the development and function of reproductive organs and the formation of secondary sex characteristics in women. It promotes breast development and the growth of the outer genitals. E2 levels vary depending on a woman's age and reproductive status. They are a good marker of ovarian function. Though considered the main sex hormones for women, they are also found in men and play a role in bone metabolism and growth in both sexes.

Note: Drug Fulvestrant will increase the apparent concentration of estradiol in women being treated with this drug.
Kindly correlate with clinical conditions.
