IMMUNOLOGY

Test Name With Methodology	Result	Unit	Biological Ref.Interval
PIVKA II ,DES-GAMMA CARBOXY PROTHROMBIN (DCP) SERUM			
DES-GAMMA CARBOXY PROTHROMBIN (DCP)/PIVKA II, SERUM (ECLIA)	30.65	ng/ml	<28.4

Note:

1. Patient samples may contain heterophilic antibodies or mouse monoclonal antibodies that could react in immunoassays to give a falsely elevated or depressed result.
2. Results should always be interpreted in conjunction with the patient's medical history, clinical presentation and other findings.
3. False low values may be observed in patients receiving vitamin K analogues.
4. False high values may be observed in patients receiving vitamin K antagonists, antimicrobial drugs, with diet low in vitamin K or in patients with ongoing alcohol intake.

Comment:

Des-gamma carboxyprothrombin (DCP) also known as PIVKA II (Prothrombin induced by Vitamin K antagonist II) is an abnormal prothrombin that is increased in the sera of patients with Hepatocellular Carcinoma (HCC). Unlike AFP, it is not elevated in Chronic Liver Disease, Cirrhosis, pregnancy or Germ Cell Tumors. It is a complementary biomarker to AFP in HCC and increases the sensitivity (83%) and specificity (84%) for HCC when used in combination. It is recommended to measure two or more different tumor markers (AFP, DCP or AFP L3) for the diagnosis of HCC at an early stage.^{1,2} DCP has also been found to correlate better with tumor size, histological grade, portal vein invasion and /or intrahepatic metastasis in patients with HCC.

Usage:

1. Risk assessment of patients with Chronic Liver Disease for development of HCC
2. To aid in the diagnosis and prognosis of patients with HCC
3. To monitor therapeutic efficacy in patients with HCC

AFP (Alpha Feto Protein)

Alpha-Fetoprotein
Serum, Electro Chemi Luminescent Immuno Assay

3.44

ng/ml

0-7

Comment:

Alpha-fetoprotein (AFP), a major plasma protein produced by the yolk sac and the liver during fetal life. In humans, AFP levels decrease gradually after birth, reaching adult levels by 8 to 12 months. Increased AFP levels may indicate the presence of cancer, most commonly liver cancer, cancer of the ovary, or germ cell tumor of the testes. However, not every liver, ovarian, or testicular cancer will produce significant quantities of AFP. Elevated levels may sometimes be seen with other cancers such as stomach, colon, lung, breast, and lymphoma. Other diseases such as cirrhosis and hepatitis can also cause increased levels. AFP is not only a tumor marker. Because AFP is produced by the fetus, levels are normally higher in pregnant women and in their newborns. Not every person with increased AFP level has cancer or will develop cancer. The AFP tests are not diagnostic; they are indicators.
